

Unveiling the kernel: Rootkit discovery using selective automated kernel memory differencing

Ahmed Zaki and Benjamin Humphrey

Agenda

- Objective and method
- System design and implementation
 - Running drivers
 - Data extraction
 - Processing the data
 - Reporting and signatures
- And the result is ...
 - Experiment A: High profile rootkits
 - Experiment B: Driver files
 - Experiment C: Random set of PE files
- Conclusion
- Future work

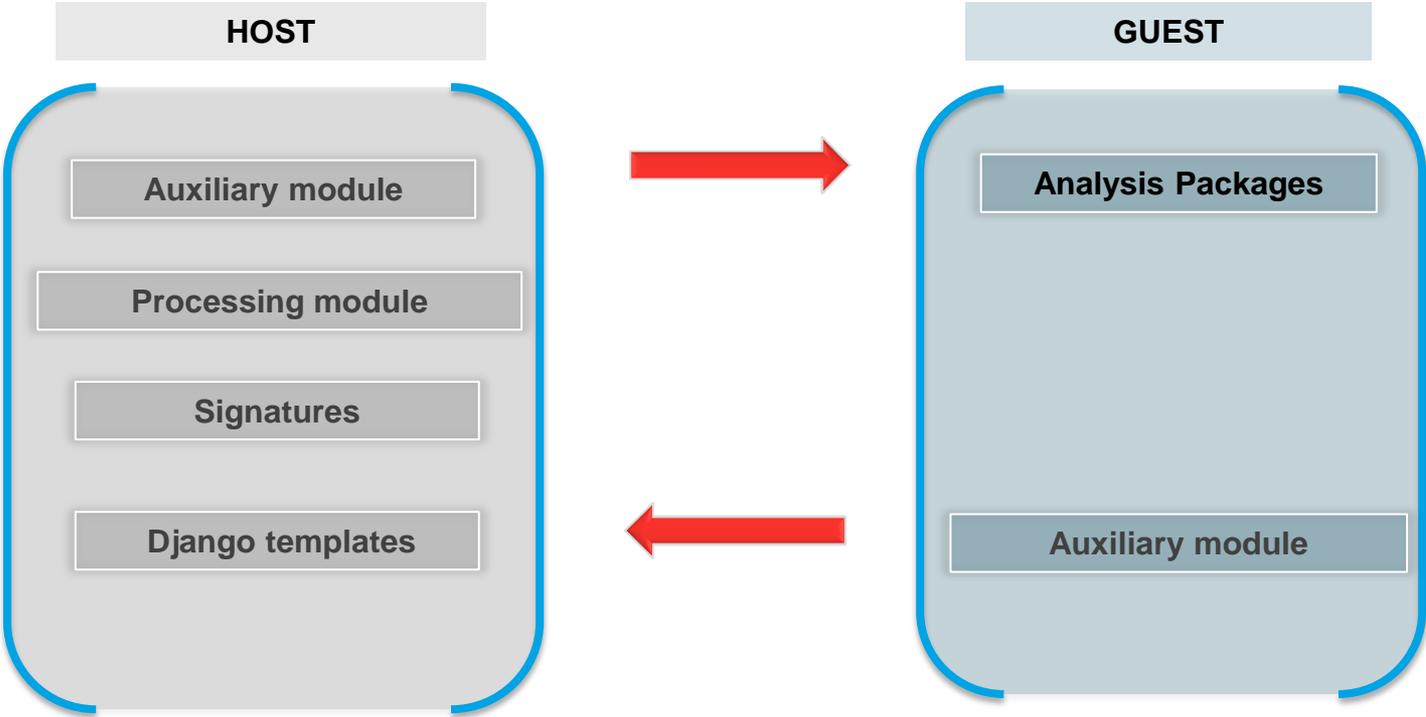

What is the objective?

- Automate the process of finding samples that exhibit kernelmode behaviour
- List the modifications made to the kernel
- Identify the maliciousness of specific modifications
- Import that data into other systems

How do we automate the process?

- Use existing tools
- Build our own
 - Using anti-rootkit tools
 - Using a custom diff based solution

Bird's eye view

Running Driver files

(Servicename | StartType | ServiceType | LoadMode)

```
“Register service using scm  
If not loadmode then:  
  start service using NTLoadDriver  
Else:  
  start service using loadmode option  
If not service is running:  
  report FAIL ! “
```

Usage of the Sophos AV Engine

With the SAV engine we get:

- Existing software that has a presence in the kernel
- The ability to examine/dump areas of kernel memory
- The ability to write to a log file

NOTE: Due to modular design we don't *need* to use the Sophos AV engine.

Examining the kernel

What areas are we looking at?

```

Name: \Driver\808a56c5daeb2cc4
Sha: None

High profile rootkits

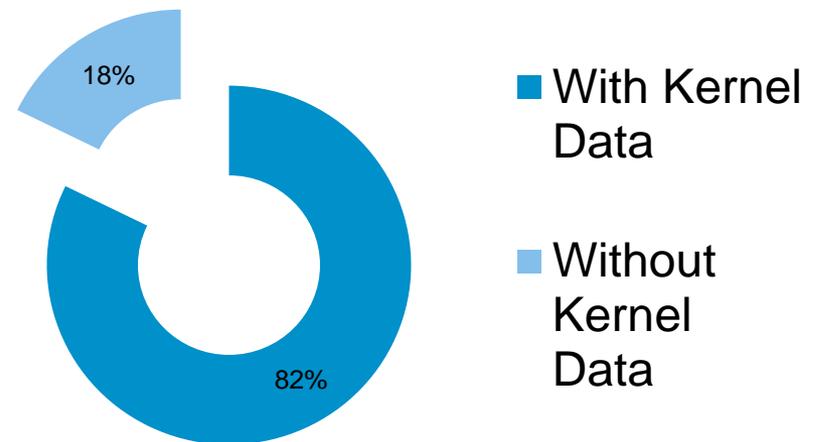

- We do not always get enough information to classify specific families
- We are getting enough information to warrant further investigation by an researcher

Experiment B

Clean Drivers

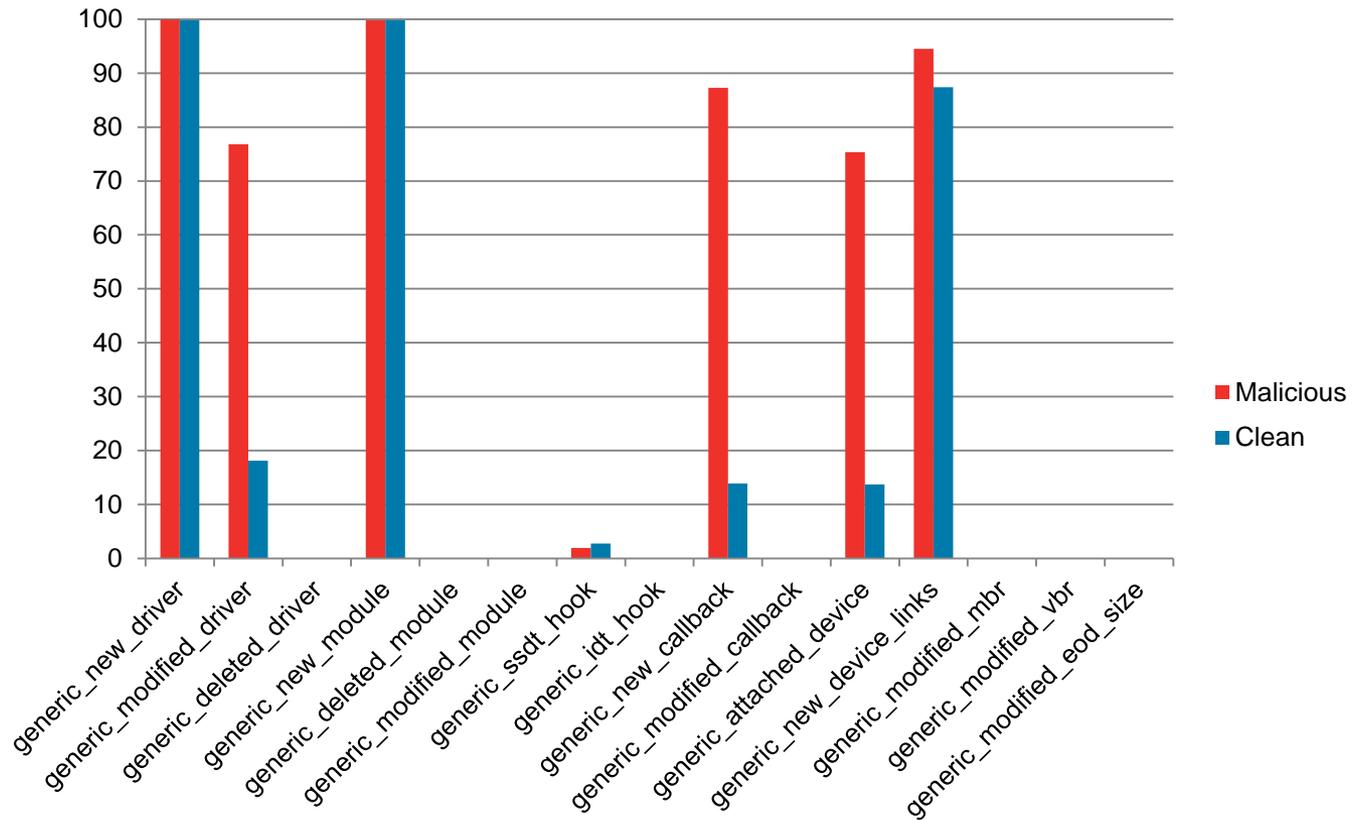

Malicious Drivers

- Total number of malicious drivers 1854.
- Total number of clean drivers 1053.
- Insufficient time for the log to be generated was a common reason for failure to get back kernel data. Miss the log by a second or two. It's a trade off.

And the results is

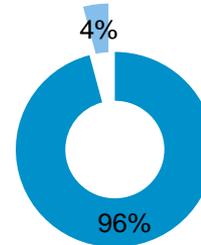

Callbacks

Experiment C

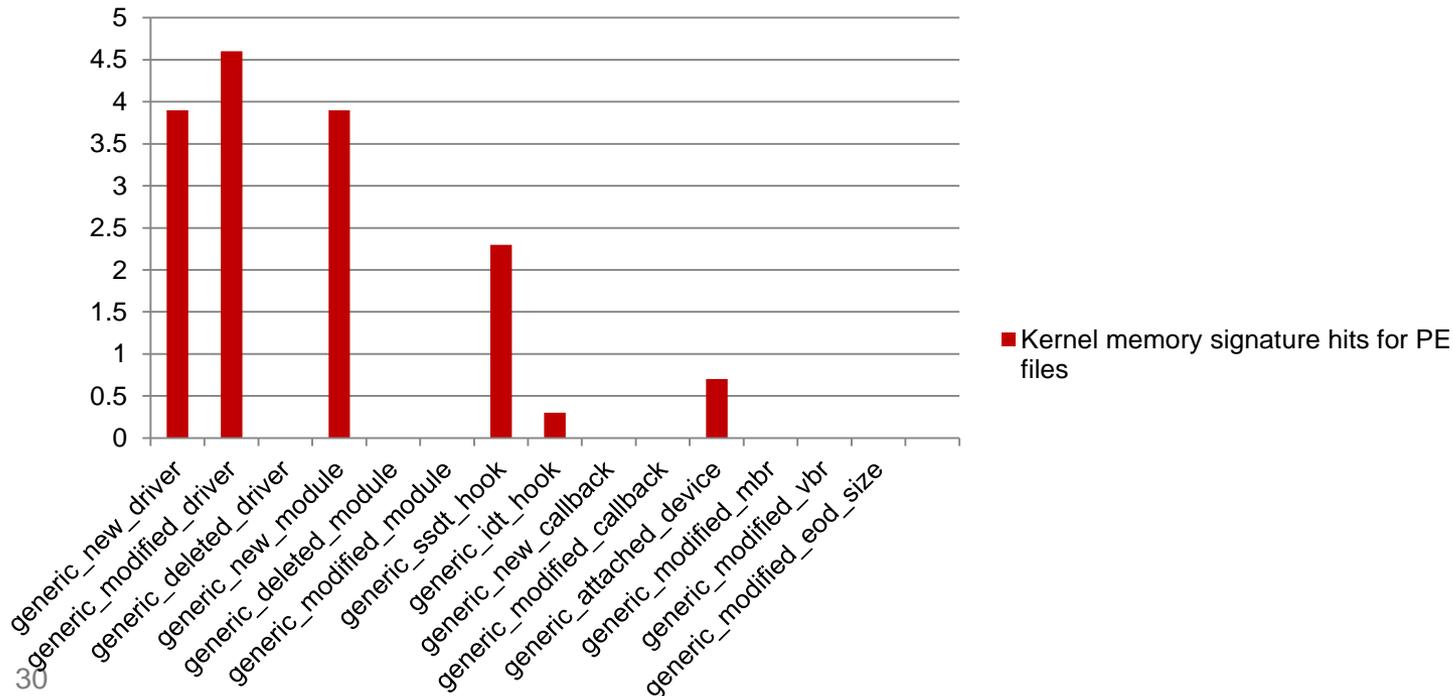

Set of PE files

- 319 of known malicious PE files.

- With Kernel memory
- Without Kernel Data

Kernel memory signature hits for PE files

Weighting the signatures

Info

New driver objects

New module

Suspicious

Modified driver

Modified module

SSDT Hook

IDT Hook

New Callback

Attached Device

Malicious

Modified MBR

Modified VBR

Modified EOD size

Conclusion

- Malicious activity can be identified via modifications rather than creation
- Malicious drivers are unlikely to employ anti-sandboxing techniques
- Good enough to identify kernel activity
 - Not exhaustive analysis

Future work

- Exploring other areas of the kernel
 - Object table
 - DKOM
 - 64bit drivers
- Sample clustering
- Usermode rootkits
