

Alureon: The First ITW 64-Bit Windows Rootkit

Joe Johnson
Software Development Engineer
Microsoft Corporation

Overview

- A crash course on TDL3, pre-MBR
- A look at the initial MBR infector and its ominous ldr64
- A deep dive into the updated version that includes 64-bit support
- A quick comparison to Sinowal
- A look into how Alureon became the first public ITW kernel rootkit to affect 64 bit Windows

Alureon\TDL3 Evolution

- Initially, TDL3 infected the resource section of the miniport driver for \Systemroot and directly replaced all the IRP handlers for it

```
DriverEntry:    f8b24380 atapi!_NULL_IMPORT_DESCRIPTOR <PERF
DriverStartIo: f8b157c6 atapi!IdePortStartIo
DriverUnload:  f8b1f204 atapi!IdePortUnload
AddDevice:     f8b1d300 atapi!ChannelAddDevice
```

Dispatch routines:

```
[00] IRP_MJ_CREATE          f8b179f2 atapi
[01] IRP_MJ_CREATE_NAMED_PIPE f8b179f2 atapi
[02] IRP_MJ_CLOSE          f8b179f2 atapi
[03] IRP_MJ_READ           f8b179f2 atapi
[04] IRP_MJ_WRITE          f8b179f2 atapi
[05] IRP_MJ_QUERY_INFORMATION f8b179f2 atapi
[06] IRP_MJ_SET_INFORMATION  f8b179f2 atapi
[...]
```

Alureon\TDL3 Evolution

- It evolved to only replace the device object in the relevant device stack and clean up the in memory image of the infected driver

```
kd> !drvobj partmgr
Driver object (82bdc3a0) is for:
  \Driver\PartMgr
Driver Extension List: (id , addr)
(f8e552d8 82bdc2b8)
Device Object list:
82b95900
kd> !devstack 82b95900
!DevObj      !DrvObj      !DevExt      ObjectName
> 82b95900   \Driver\PartMgr  82b959b8
  82b0aab8   \Driver\Disk    82b0ab70     DR0
  82be0f18   \Driver\ACPI    82b98008     00000050
Invalid type for DeviceObject 0x82b91940
```

Alureon\TDL3 Evolution

- Eventually, it started infecting random drivers instead of the miniport driver it targeted in memory
- On 7/19/2010 we received our first sample of a new version that infects the MBR instead of a driver

First MBR-infecting Alureon

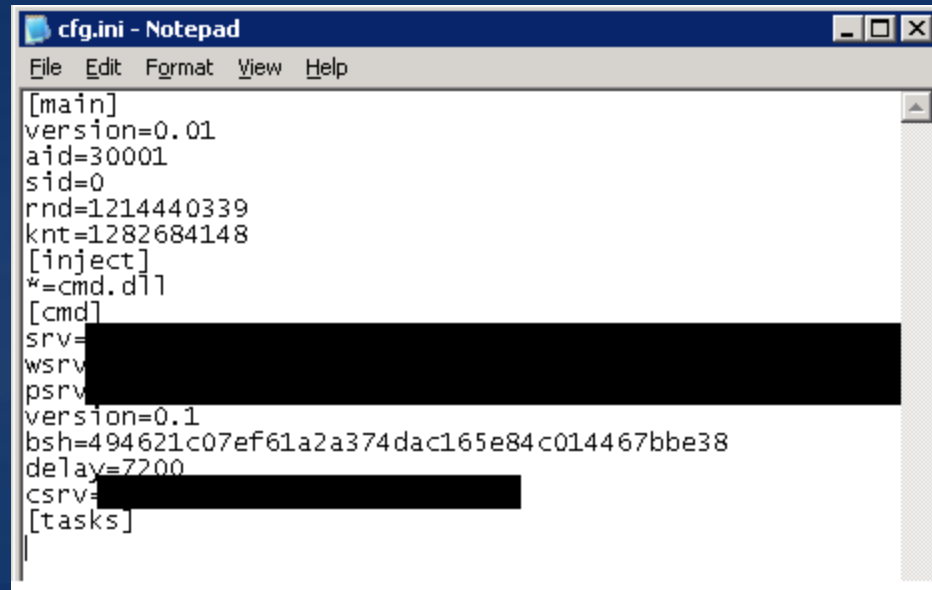

Something old, something new.

- Still infects the device stack for the drive containing \Systemroot
- Still has everything except the initial loading code in an encrypted virtual file system at the end of the disk
- Still installs via driver loaded by the spooler
- Now loads via an infected MBR instead of an infected driver

First MBR-infecting Alureon

Something old, something new.

- The MBR variant uses a config file as well, but now the version is 0.01 instead of 3.27.3, indicating a version under development

```
cfg.ini - Notepad
File Edit Format View Help
[main]
version=0.01
aid=30001
sid=0
rnd=1214440339
knt=1282684148
[inject]
*=cmd.dll
[cmd]
srv=

[tasks]
```

First MBR Infecting Alureon

Contents of the virtual file system

- mbr – Copy of the original mbr
- ldr16 – Int 13h hook and loader for ldr32
- ldr32 – Fake KD (kernel debugger communication DLL)
- drv32 – Payload driver. Handles hooking device stack for \SystemRoot and injecting processes
- Cfg.ini – Configuration file
- ldr64 – Uh... ???

First MBR Infecting Alureon

ldr64 empty! Phew!

```

MBR Alureon 0.02

The 64-bit Rootkit

- First appeared on 8/9/2010
- Ldr64 is no longer empty and 64 bit version of the payload driver is now also present
- Because of Code Integrity, the print spooler driver load no longer works, so it writes to disk the old fashioned way

How Does It Load?

MBR

- The MBR starts with boilerplate relocation code to move to 0x600
- After jumping to the relocated code, it runs a simple ROR decryption loop (only 12 bytes of code)
- It then decrypts and loads ldr16 from the VFS

How Does It Load?

Ldr16 – int13h hook

- The first thing Ldr16 does after loading is to hook int13h, the BIOS disk read interrupt
- After starting the normal load sequence, it watches for the load of a KD communication extension (usually kdc.com.dll), and replaces it with Ldr32 or Ldr64 depending on the PE

```
xor     si, si
mov     es, si
mov     eax, es:[si+4Ch]
mov     dword ptr ds:call_original_int13+1, eax
mov     ah, 48h ; 'H'
mov     si, 4F6h
mov     word ptr ds:4F6h, 1Eh
int     13h ; DISK -
xor     di, di
mov     word ptr es:[di+4Ch], offset loc_3F
mov     word ptr es:[di+4Eh], cs
```

Name	RVA	Size
Export	00001060	000000FA
Import	000019FC	00000028
Resource	00000000	00000000

How Does It Load?

Finding kdcom.dll

```
seg000:0112 ReplaceKdcom: ; CODE XREF: seg000:00BA↑j
seg000:0112      cmp     word ptr es:[bx], 5A4Dh ; M2
seg000:0117      jnz     DoHooks
seg000:0118      mov     di, es:[bx+3Ch]
seg000:011F      cmp     word ptr es:[bx+di], 4550h ; PE
seg000:0124      jnz     DoHooks
seg000:0128      cmp     word ptr es:[bx+di+18h], 10Bh ; Look for 32bit optional header size
seg000:012E      jnz     short ReplaceKdcom64
seg000:0130      cmp     dword ptr es:[bx+di+7Ch], 0
seg000:0136      jz      short loc_106
seg000:0138      cmp     dword ptr es:[bx+di+7Ch], 0FAh ; ''
seg000:0141      jnz     DoHooks
seg000:0145      mov     si, offset aLdr32 ; "ldr32"
seg000:0148      mov     cx, 6
seg000:014B      jmp     short ReadUfsFile
seg000:014D ; -----
seg000:014D ReplaceKdcom64: ; CODE XREF: seg000:012E↑j
seg000:014D      cmp     dword ptr es:[bx+di+8Ch], 0
seg000:0154      jz      short loc_FA
seg000:0156      cmp     dword ptr es:[bx+di+8Ch], 0FAh ; ''

seg000:0164      mov     si, 3BFh
seg000:0167      mov     cx, 6
seg000:016A ReadUfsFile: ; CODE XREF: seg000:014B↑j
seg000:016A      cld
```

How Does It Load?

Other int13h patches

- The first block swaps the EmsEnabled library flag (0x16000020) in the BCD to be the WinPEMode OS Loader flag (0x26000022)

```
DoHooks:                                     ; CODE XREF: s
                                             ; seg000:00061
        movzx  cx, byte ptr ds:3E1h
        shl   cx, 7

PatchBcd2Pe:                                 ; CODE XREF: s
        cmp   dword ptr es:[bx], '0061'
        jnz   short patchEmsToApp
        cmp   dword ptr es:[bx+4], '0200'
        jnz   short patchEmsToApp
        mov   dword ptr es:[bx], '0062'
        mov   dword ptr es:[bx+4], '2200'
```

How Does It Load?

Other int13h patches continued

- The second block tweaks the parent of the EmsEnabled Library flag to allow the WinPEMode OS loader flag to work

```
patchEmsToApp:                                ; CODE XREF: s
                                                ; seg000:0238T
        cmp     dword ptr es:[bx], 1666Ch
        jnz     short KillMin
        cmp     dword ptr es:[bx+8], '0061'
        jnz     short KillMin
        mov     dword ptr es:[bx+8], '0062'
```

How Does It Load?

Other int13h patches continued

- The third block changes the string `"/MIN"` to `"IN/M"`, hiding the normal registry option of `"/MININT"` that would be visible for a WinPE boot.

```
KillMin:                                ; CODE XREF: sec
                                           ; seg000:025E1j
      cmp     dword ptr es:[bx], 'NIM/'
      jnz     short next
      mov     dword ptr es:[bx], 'M/NI'
```

How Does It Load?

Ldr64 fake KD communications DLL

- The kernel loads the fake version of kdcom thanks to the int13h hook
- Most of the debugging operations are set to return safe values, but KdDebuggerInitialize1 has the first link in the (long) loading chain

```

Differences From Sinowal

- While both follow the MBR -> 16 bit loader pattern, they take different approaches after that
- Sinowal hooks the kernel to install its driver loader, then hooks IoInitSystem to load its driver after the rest of the drivers are loaded
- Alureon replaces the debugging infrastructure and relies on built in kernel routines to do the work thereafter

How About Patchguard?

- 64 bit Alureon does not bypass Kernel Patch Protection (Patchguard)
- Patchguard only guards the code and structures used by the kernel, not all loaded drivers
- The drv64 payload, once loaded, behaves in a way consistent with normal third party extensibility in the kernel

What About Code Integrity?

No, seriously, how *does* it load?

- In this case, the BCD was patched to inform winload that this is Windows PE booting, not a normal version of Windows
- Winload does not check code integrity in this case
- As seen before, the malware also trashes the `"/MININT"` string which prevents the rest of Windows from treating the OS instance as WinPE

What About Windows XP-64?

- In the case of Windows XP-64 and Server 2003 64-bit, the fake version of kdcom.dll breaks the boot sequence
- This renders the machine unbootable

```
Windows could not start because of an error in the software.  
Please report this problem as :  
load needed DLLs for kernel.  
Please contact your support person to report this problem.
```

Detection

- Detected as
 - Trojan:Win32/Alureon.DX (Dropper)
 - Trojan:DOS/Alureon.A (MBR\Rootkit)
- Infected machines also no longer list the system disk in diskpart

```
Administrator: cmd - diskpart
Microsoft Windows [Version 6.1.7600]
Copyright (c) 2009 Microsoft Corporation. All rights reserved.

C:\Windows\system32>diskpart

Microsoft DiskPart version 6.1.7600
Copyright (C) 1999-2008 Microsoft Corporation.
On computer: TEST-PC

DISKPART> lis dis

There are no fixed disks to show.
DISKPART>
```

Cleanup

- Since the only trace of the infection outside the virtual file system is the MBR, that is all that needs to be disabled
- Online cleaning is problematic, but currently offline cleaning is trivial. Use fixmbr for XP/Server 2003 (32 and 64 bit), and bootrec for Vista+. Future variants may break this.

Conclusions

- As of July 2010, 46% of Windows 7 machines are 64-bit
- Server 2008 R2 only supports 64-bit
- As more machines move to 64-bit Windows, we can expect more malware to move into the 64-bit kernel

Thanks to Scott Molenkamp, Jimmy Kuo, Vincent Tiu, Mady Marinescu for their help on this presentation.
